ABSTRACT

An index to the 1962 mourning dove breeding population was obtained by a call-count survey conducted throughout the United States. Trends in the breeding population index were calculated for three management units and for hunting and nonhunting States within the management units. Trends in the breeding population indexes from 1961 to 1962 were as follows: Eastern Unit down 3 percent, Central Unit down 11.5 percent, and Western Unit down 12 percent. For the United States as a whole, the 1962 breeding population index is down 10 percent from 1961.

INTRODUCTION

Prior to 1960, the annual status of the mourning dove population was reported in the Mourning Dove Newsletter. The Newsletter continues as a report on activities in mourning dove research and management on a national scale, but the annual report on status of the population, used chiefly for regulatory purposes, is published separately. The 1960 and 1961 Status Reports were published in the Special Scientific Report - Wildlife Series Nos. 49 and 57.

An annual survey of the breeding population of mourning doves by a system of call-count routes provides an index to the status of the population in the United States. Through the cooperation of State, Bureau, and independent observers, call-count routes were widely established by 1953. The hundreds of cooperators who participate in the call-count survey have contributed the data that form the basis for this report.

The call-count survey period is May 20 - June 10, a period during which dove calling activity is relatively stable, as indicated by intensive studies in eastern United States (Special Scientific Report - Wildlife No. 17). Because hunting regulations must be published 30 days prior to the hunting season, the Dove Regulations Committee can meet no later than in late June. Status statistics must be summarized for consideration by this Committee. The annual Status Report (or a preliminary version thereof) serves this purpose. It also is distributed to all cooperators in the call-count survey and is available to interested organizations and individuals.

For several years prior to 1960, the Federal framework of mourning dove hunting regulations was established on the basis of eastern and western groups of States. Recent analysis of banding data indicates that there are three units of the mourning dove population in the United States that are largely independent of each other (Kiel, 1959) and the Federal framework of hunting regulations was established on the basis of these three management units in 1960. The criteria for independence are that a unit produces the bulk of the doves that it harvests and does not produce a significant number of doves that are harvested by other units. The Eastern, Central, and Western Management Units outlined in figure 1 best meet

these criteria for management units on the basis of present information. Additional analysis of banding data is currently in progress to more firmly establish the Management Unit boundaries.

PROCEDURE

The Call-count Method

Call-count routes were established after field investigations in 1950-51 demonstrated the feasibility of the technique. These investigation were reported by Foote, Peters, McGowan, Kerley, Duvall, Robbins, and Wagner (1952). Doves heard calling and doves seen are recorded on a route 20 miles in length with listening stations one mile apart. Call counts begin one-half hour before sunrise and continue for two hours. Information on the call-count method and procedures for randomly selecting call-count routes was presented by Foote, Peters, and Finkner (1958).

The call-count survey provides the only population index for doves currently available on a national and international scale. It has limitations and possible biases that require consideration and evaluation through further study. It is an index to the breeding population only and does not indicate production. This is an important limitation because a high percentage of an average fall population is composed of young of the year. In calculating trends in the breeding population, doves heard calling has been a less variable index than doves seen. Additional research is needed to understand the relationship of doves heard calling and doves seen to the actual population in various portions of the mourning dove breeding range. Several Cooperative Wildlife Research Units and State and Bureau Personnel are conducting studies of the call-count census method this year.

Weighting Factors

When combining data from several States to obtain breeding population indexes for management units or parts of management units, it was necessary to give appropriate weight to the data from each State. This was done by multiplying the average doves heard calling per route in each State by the estimated area of dove habitat in the State to obtain a breeding population index value. These index values for each State were then added together to obtain the properly weighted breeding population index for the combination of States. This weighting procedure recognizes differences between States both in dove density and the amount of habitat. Dove habitat area was estimated in the 1958 Mourning Dove Newsletter and is listed in table 1.

Long-term Trends

For the purpose of showing long-term trends in the breeding population index of a State, a base year was selected, and annual percentage changes have been applied to the base figure (average doves heard calling per route) to give an adjusted figure which shows the true relation of indexes from year-toyear. The selection of a base figure is necessary because not all routes are censused each year. From a base year, average doves heard calling per route for each State has been adjusted annually according to the percentage change from the preceding year in counts on routes covered both years. For example, 1957 was selected as a base year in Alabama (table 2). In that year, the average doves heard calling per route was 21.1. In 1958, the percentage change from 1957 in counts on comparable routes was an increase of 12.8 percent, so the base figure of 21.1 was adjusted upward by 12.8 percent to a level of 23.8. In 1959, the percentage change from 1958 in counts on comparable routes was a decrease of 21.6 percent, so the 1958 adjusted figure or adjusted base was decreased by 21.6 percent, from 23.8 to 18.7.

TRENDS IN THE BREEDING POPULATION INDEX - 1962

Eastern Management Unit

The breeding population index for the Eastern Unit decreased 3 percent from the 1961 level (table 1). Figure 2 shows that the breeding index of the Eastern Unit increased generally over the 7-year period prior to 1961, followed by a 2-year decline.

In hunting States of the Eastern Unit, the breeding index remained unchanged from 1961. In nonhunting States, the index decreased 12 percent from 1961 to 1962 (table 1). The long-term trend of the breeding index in nonhunting States of the Eastern Unit is shown in figure 3 and indicates a relatively stable population in recent years.

Central Management Unit

The breeding population index for the Central Unit decreased 11.5 percent from the 1961 level (table 1). Figure 2 shows that for 6 years up to 1960 the breeding index of the Central Unit generally increased. This has been followed by declines in 1961 and 1962.

Figure 2. Trends in Breeding-population Indexes by Management Units, 1953-1962

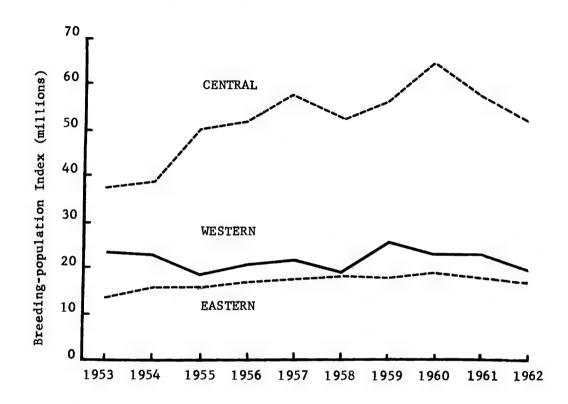

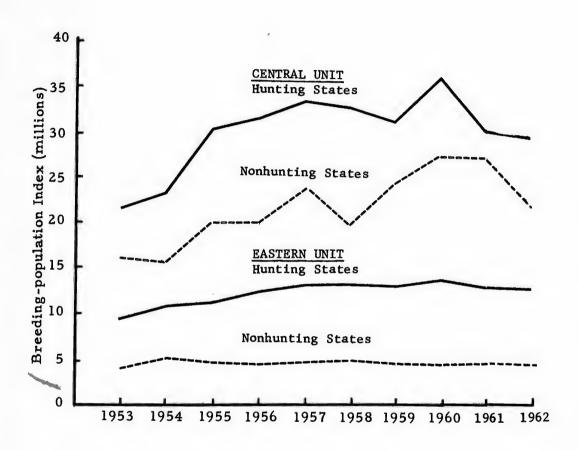

Figure 3. A Comparison of Trends in Breeding-population Indexes for Hunting and Nonhunting States within Management Units.

In hunting States of the Central Unit, the breeding index decreased 4 percent compared to 1961. The State of Texas had two routes that were not considered in the 1962 data because they so heavily weighted the data for Texas that the State index was altered -22.6 percent (from +4.3 to -18.3 percent change). This in turn altered the entire Central Management Unit data (from -11.5 to -15.8 percent change).

In nonhunting States, the index declined 20 percent between 1961 and 1962 (table 1). Adverse weather was reported as occuring during the census period in the north central area of this management unit in 1962. To test the influence that unseasonable weather had on these counts, the records of weather conditions taken at the time of beginning of the routes was compared for the years 1961 and 1962 in the States of Iowa, Minnesota, Nebraska, South Dakota, and North Dakota. Average temperature, percent cloudiness, and the Beaufort wind scale were measurements used. No clear-cut weather differences were noted between years except greater cloudiness occurred in 1962 reflecting the reported stormy conditions. Cloudiness, by itself has not proven to be a cause of decreased calling intensity.

Western Management Unit

The breeding population index for the Western Unit showed a 12 percent decrease from the 1961 level (table 1). Figure 2 shows that the breeding index of the Western Unit has fluctuated moderately over the 10-year period at generally stable levels.

Discussion of Population-index Trends

Indexes to mourning dove breeding populations in the three management units showed declines from the 1961 level. For the United States as a whole, the 1962 breeding population index was 10 percent below the 1961 level. The long-term trend has been generally upward since 1953 to 1960 and has decreased in 1961 and 1962. The breeding population index level in the Eastern and Central Units remain above the 1953 levels and in the Western Unit the index fluctuated above and below its present level since 1953.

^{*} From a base year, average doves heard calling per route for each State has been adjusted annually according to the percentage change from the preceding year in counts on comparable routes. The index, expressed in thousands, is the product of the adjusted average doves heard per

route and the estimated area of dove habitat.

The area of dove habitat has not been estimated for Maine, New Hampshire, Rhode Island, and Vermont.

pole 2. Trends in the Breeding-population Index, 1953-62

The first figure listed for each State by years is the adjusted average doves heard calling per route. The method of adjustment is described in the text. The base year for adjustments was 1956 or 1957. States for which 1957 was the base year are those that reorganized call-count routes in that year. These States are Alabama, Georgia, Kentucky, Mississippi, North Carolina, South Carolina, and Tennessee.

The second figure for each State is the breeding-population index. The index, expressed in thousands, is the product of the adjusted average doves heard per route and the estimated area of dove habitat. (Habitat area is given in table 1.)

PERCEI CHANGE		+3.6	+10.2	+3.8	+8.8	-7.3	+10.8	+5.9	-6.6	-10.

^{*} The 1953 index is incomplete because Colorado, Utah, and Wyoming did not conduct call-count surveys until 1954. The percentage change from 1953 to 1954 is based on comparable data only.

^{**} Maine, New Hampshire, Rhode Island, and Vermont first established call-count routes in 1959. No estimate has been made of the square miles of dove habitat in these States.

Table 3. Summary of Call-count Routes by States.

Includes all routes run in 1962 but only comparable routes for 1961.

The Department of the Interior, created in 1849, is our Nation's Department of Natural Resources, concerned with management, conservation, and development of water, wildlife, fish, mineral, forest, and park and recreational resources. It also has major responsibilities for Indian and Territorial affairs.

As America's principal conservation agency, the Department works to assure that nonrenewable resources are developed and used wisely, that park and recreational resources are conserved for the future, and that renewable resources make their full contribution to the progress, prosperity, and security of the United States, now and in the future.

UNITED STATES DEPARTMENT OF THE INTERIOR Stewart L. Udall, Secretary

Frank P. Briggs, Assistant Secretary for Fish and Wildlife
FISH AND WILDLIFE SERVICE
Clarence F. Pautzke, Commissioner
BUREAU OF SPORT FISHERIES AND WILDLIFE
Daniel H. Janzen. Director
